Trading Performance Analysis Report

A Quantitative Review of Trade Outcomes, Risk Management, and Execution Discipline

Item	Detail
Prepared for	Portfolio Demonstration
Dataset	40 Simulated Trades (fictional)
Period covered	2026-03-02 to 2026-04-28 (fictional dates)
Instruments	XAUUSD, EURUSD, GBPUSD, USDJPY, BTCUSD (fictional price levels)
Starting equity	USD 10,000 (fictional account)
Unit of account	R-multiples (1R = planned risk on the trade) and USD

This document is a simulated case study built to demonstrate the structure and method of a trading performance audit. Every trade, date, price, account figure, and rule flag was generated for this demonstration. Nothing here is a verified trading record, a client result, or evidence that any strategy is or will be profitable.

SIMULATED CASE STUDY - FICTIONAL DATA - NOT ACTUAL CLIENT RESULTS

Educational and analytical sample. Not investment advice. No real trades, clients or accounts are depicted.

Section 1. Executive summary

40	45.0%	1.17	+4.12R	-3.74R
Simulated trades	Win rate (18W / 22L)	Profit factor (R basis)	Net result (+$144.47 USD)	Max drawdown (-3.95% of equity)

What the data shows. Across 40 simulated trades between 2026-03-02 and 2026-04-28, the account finished +4.12R higher after transaction costs (USD 144.47; 1.44% on USD 10,000). The win rate was 45.0%, winners averaged +1.54R and losers -1.07R, giving a profit factor of 1.17 (R basis) or 1.07 (USD basis). Maximum drawdown was 3.74R, which corresponded to 3.95% of peak account equity (the two measures are different and peak at different trades; see Section 4).

Risk and discipline. 4 of 40 trades (10%) were sized above their planned risk; two of these were within a 10% tolerance and two were not. 8 trades (20%) carry a documented rule violation and 2 records (5%) are unclear because supporting evidence is missing.

Most important findings.

- The average result of +0.103R per trade is positive but small; its 95% confidence interval (-0.33R to +0.54R) includes zero, so this sample cannot distinguish the result from chance.
- Trades flagged for rule violations averaged -0.39R versus +0.31R for unflagged trades, but the groups are small (8 and 30 trades).
- The two trades sized beyond tolerance produced the two largest losses in R, and the three trades on 24 March produced almost the entire maximum drawdown.
- Setup, session, instrument and direction differences are visible but every group has fewer than 30 trades, so none can be treated as a reliable ranking.

What remains uncertain. Whether the strategy has any real edge, whether rule violations cause weaker results, and whether any segment genuinely outperforms. Answering those needs a larger real record, a written trading plan dated before the trades, and execution data (slippage, fills, order history).

Section 2. Dataset overview and methodology

Contents. The dataset has 40 trades, one row each, with 19 required fields (identifiers, date, instrument, session, setup, direction, entry, stop, take-profit, planned and actual risk, gross and net P/L, costs, R-multiple, outcome, risk-exceeded flag, rule flag, notes) plus six supporting fields (exit price, exit type, position exposure, equity before the trade, 1R in USD, and rule IDs). The full table is in the accompanying Excel and CSV files and in Appendix A.

Definition of 1R. 1R is the planned amount of money at risk on a trade: planned risk percentage x account equity immediately before the trade. Most trades planned 1.00% of equity; BTCUSD trades planned 0.50% because of wider stops. Net result in R = net P/L (USD) / 1R (USD).

How the records were generated. Dates, prices and position sizes were generated by a script so the numbers are internally consistent: exposure (USD per 1.0 price unit) = planned risk in USD x size multiplier / stop distance; gross P/L = exposure x signed price move from entry to exit; net P/L = gross P/L - transaction costs. Instruments, sessions, setups and directions were drawn with a fixed random seed. **The outcome of each trade and the rule flags were authored by the report preparer, not produced by a market model**, so the comparisons in this report demonstrate analytical technique; they are not discoveries about markets.

Costs and execution. Transaction costs are modelled as a round-turn spread (price units) x exposure. Commissions, swaps, financing and currency conversion are not modelled. Slippage appears only where an exit is recorded beyond the stop (T14 and T31). Position exposure is expressed in USD per 1.0 price unit, which sidesteps lot-size and pip-value conventions; this is a simplification.

Calculations performed. Win/loss counts, win rate, profit and loss totals, profit factor, payoff ratio, expectancy, standard error and 95% confidence interval of expectancy (t-distribution, 39 degrees of freedom), cumulative R, running peak, drawdown in R, USD and percent of equity, streaks, planned versus actual risk, and segment tables.

Every figure was recomputed with an independent plain-Python script from the exported CSV; all matched (Appendix B).

Classification rules. A trade is a win if net P/L (after costs) is above zero and a loss if below zero; no trade closed at exactly zero. Profit and loss totals are therefore stated after costs. Pre-cost totals are shown separately in Section 3 so the two reconcile.

Documented rules used for the audit (hypothetical written plan).

- **R1** Position size must be within 10% of planned risk.
- **R2** Trade only the London, New York and overlap sessions; the Asian session is permitted for USDJPY only.
- **R3** Enter only after the confirmation candle closes.
- **R4** Exit only at the stop, the target, or a documented trailing stop (no undocumented discretionary exits).
- **R5** After two consecutive losses in a day, stop trading for that day.

Data-quality limitations. Three trades have no fixed take-profit because they used a documented trailing exit (shown as N/A, not missing). Two records (T12, T37) lack evidence to confirm whether the stop was moved and are labelled Unclear rather than Yes or No. Fields such as fill times, order tickets and screenshots do not exist in this synthetic set.

Section 3. Performance analysis

Metric	Formula	Substituted values	Result
Win rate	Wins / Trades x 100	18 / 40 x 100	45.0%
Profit on winning trades (R)	Sum of R on winners	18 winners	+27.69R
Loss on losing trades (R)	Sum of R on losers	22 losers	-23.57R
Net result (R)	Profit - |Loss|	27.69 - 23.57	+4.12R
Profit on winners (USD)	Sum of net USD on winners		$2,315.11
Loss on losers (USD)	Sum of net USD on losers		-$2,170.64
Net result (USD)	Profit - |Loss|	2,315.11 - 2,170.64	$144.47
Profit factor (R)	Profit / |Loss|	27.69 / 23.57	1.17
Profit factor (USD)	Profit / |Loss|	2,315.11 / 2,170.64	1.07
Average winning trade	Winner R / Wins	27.69 / 18	+1.54R ($128.62)
Average losing trade	Loser R / Losses	-23.57 / 22	-1.07R (-$98.67)
Average win : average loss	Avg win / |Avg loss|	1.538 / 1.071	1.44
Expectancy per trade	Net R / Trades	4.12 / 40	+0.103R ($3.61)
Break-even win rate	1 / (1 + payoff ratio) x 100	1 / (1 + 1.44)	41.1%
Largest win / largest loss	Max and min net trade		+2.16R ($215.97) / -1.54R (-$154.62)
Longest win / loss streak	Consecutive trades		2 wins / 3 losses
Pre-cost P/L, costs, net (USD)	Gross - Costs = Net	239.30 - 94.83	$144.47

Table 1. Principal metrics. Win/loss counts reconcile (18 + 22 = 40); winners plus losers equal the net result in both R and USD. n = 40 simulated trades.

Why win rate alone is not enough. A trader who wins 70% of trades can lose money if the average loss is much larger than the average win, and a trader who wins 35% can be profitable if winners are large. Here the win rate is 45.0%, but what matters is its relation to the payoff ratio: with winners averaging 1.44 times the size of losers, the break-even win rate is 41.1%. The simulated result sits only 3.9 percentage points above that line, which is a thin margin.

Costs and expectancy. Transaction costs totalled USD 94.83, about 1.02R, or 20% of the pre-cost result of +5.14R. Average cost was about 0.025R per trade. Losses average slightly more than 1R (-1.07R) partly because

costs are added to every stop-out and partly because of two slippage trades and two oversized trades. Expectancy is the single number that combines win rate, payoff and costs: it is the average R gained per trade.

Precision of the estimate. The standard deviation of trade results is 1.35R, so the standard error of the mean is 0.21R and the 95% confidence interval for expectancy is -0.33R to +0.54R. A positive point estimate does not establish an edge when the interval spans zero. Because the profit factor is calculated on the same 40 results, it carries similar uncertainty.

R basis versus USD basis. The profit factor is 1.17 in R and 1.07 in USD. They differ because BTCUSD trades risk 0.5% (half the USD at stake of other trades), account equity changes over time, and BTCUSD trades were comparatively favourable in R. R measures decision quality independent of size; USD measures what the account actually experienced.

Section 4. Equity curve and drawdown analysis

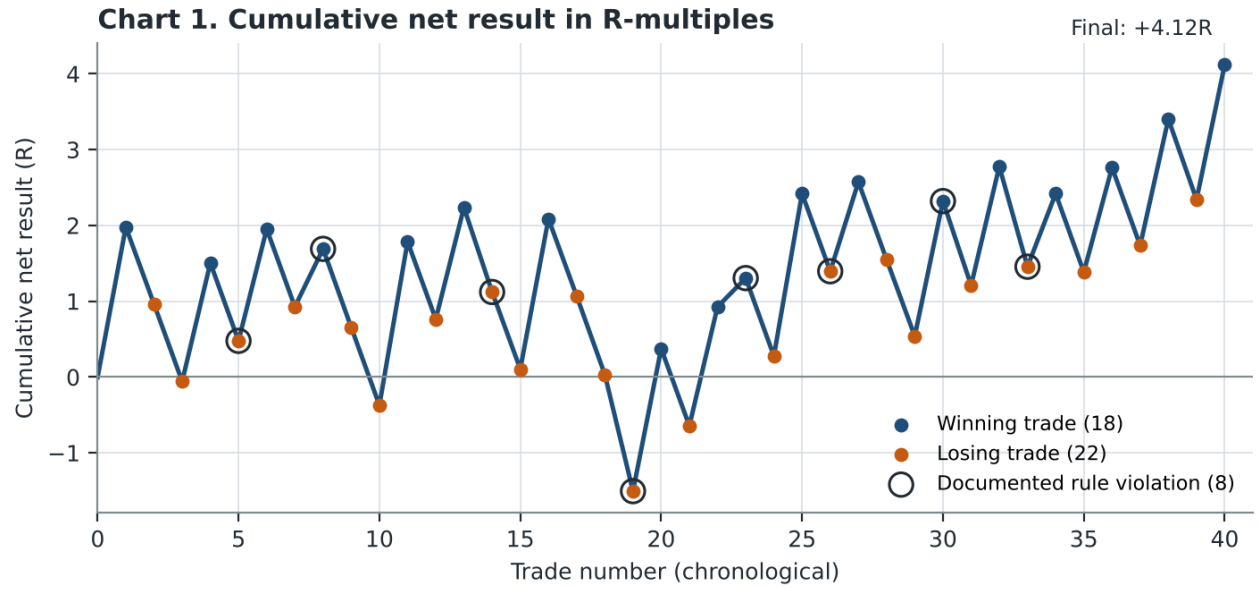

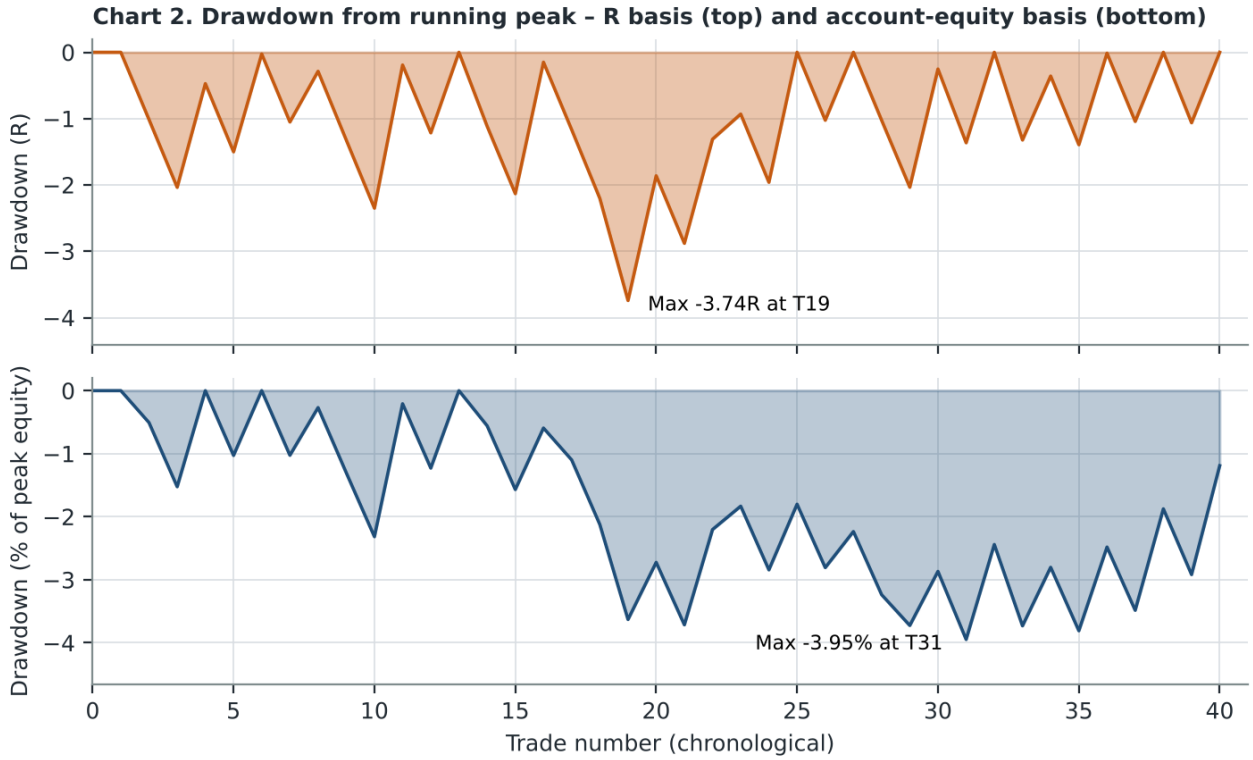

Chart 1. Cumulative net result in R-multiples across 40 simulated trades, chronological order. Circled points are documented rule violations.

Progression. Cumulative R rose to +1.98R after the first trade, fell to roughly zero by T03, recovered to +2.24R at T13, then dropped to its low of -1.51R at T19. From T20 the curve recovered and ended at +4.12R. The path is jagged: no single stretch of more than 2 consecutive wins occurred, and the longest losing run was 3 trades (T17 to T19).

Simulated data – n = 40 trades · starting equity USD 10,000 · the two panels use different units and are not interchangeable

Chart 2. Drawdown from the running peak. Top: in R. Bottom: as a percentage of peak account equity. Different units; do not compare the numbers directly.

Maximum drawdown. Measured in R, the largest peak-to-trough decline was 3.74R, from the cumulative peak after T13 to the trough at T19. Measured on the account, the largest decline was $405.19 or 3.95% of the peak equity of $10,266.68, with the trough at T31. The two measures differ because 1R is a variable dollar amount (it scales with equity and with the planned risk percentage) and because the equity drawdown continued to deepen at T31 even though the R-based drawdown had already begun to recover. Drawdown in R must not be read as a percentage of the account.

Interpretation limits. This curve describes 40 simulated trades. It does not forecast future performance, and a similar-looking curve could arise from a strategy with no edge.

Section 5. Risk-management assessment

Trade	Planned risk	Actual risk	Size vs plan	Net result	Documented rule status
T19	1.00%	1.50%	+50%	-1.54R (-$154.62)	Violation (R1)
T25	0.50%	0.54%	+8%	+2.14R ($106.90)	Within 10% tolerance
T33	1.00%	1.30%	+30%	-1.32R (-$132.46)	Violation (R1)
T39	1.00%	1.04%	+4%	-1.06R (-$107.07)	Within 10% tolerance

Table 2. The 4 trades whose actual risk exceeded planned risk. n = 4 of 40. T19 also breached R5.

Planned versus actual risk. Average planned risk was 0.887% of equity and average actual risk 0.909%. 4 trades (10%) exceeded plan: T25 and T39 by small amounts that fall inside the 10% tolerance, and T19 (+50%) and T33 (+30%) by amounts that breach rule R1.

What the numbers do and do not say. T19 (-1.54R) and T33 (-1.32R) are the two largest losses in the dataset. Arithmetically, the same price moves at the planned size would have produced about -1.03R and -1.02R. That is a statement about size, not about cause: the breach did not cause the stop-out, it enlarged the loss once the stop was hit. Whether oversizing contributed to the drawdown beyond that depends on why it happened, which the records do not explain.

How a real analyst would investigate.

- **Position sizing:** compare order tickets with the sizing calculator or spreadsheet used, check whether equity or stop distance was misread, and look for a pattern (time of day, after losses, instrument).
- **Stop-loss changes:** compare the stop recorded at entry with the stop in the broker's order history; a stop widened after entry increases real risk without changing the recorded size.
- **Execution differences:** use fill timestamps and prices to separate slippage and spread widening from deliberate decisions (T14 and T31 show exits beyond the stop).
- **Incomplete records:** treat missing entries (T12, T37) as open questions, not as findings, and request the supporting evidence.

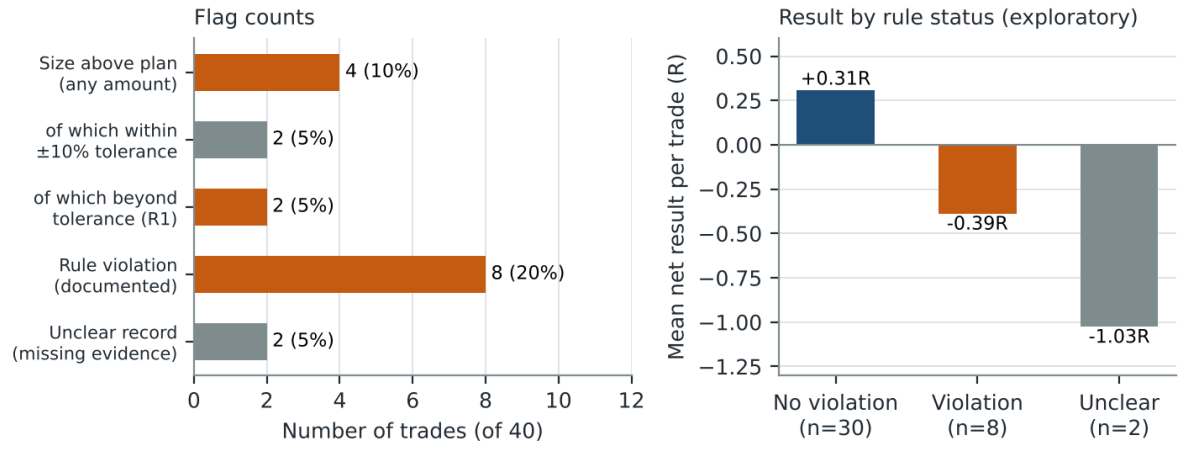

Section 6. Trading-rule adherence

Trade	Status	Rule	Net result	Evidence recorded
T05	Yes	R3	-1.03R	Entered before confirmation candle closed; stopped out
T08	Yes	R4	+0.76R	Closed manually well before target; no trail documented
T12	Unclear	R4?	-1.02R	Journal does not say whether stop was moved; record incomplete
T14	Yes	R2	-1.11R	Asian-session entry on non-JPY pair; gap through stop (slippage)
T19	Yes	R1, R5	-1.54R	Third trade of the day after two losses; position oversized
T23	Yes	R4	+0.38R	Manual early exit at small gain; no trail documented
T26	Yes	R2	-1.02R	Asian-session entry on non-JPY pair
T30	Yes	R3	+1.78R	Entry without confirmation; trade still reached +1.8R
T33	Yes	R1	-1.32R	Position size above plan by ~30%
T37	Unclear	R4?	-1.03R	Exit screenshot missing; cannot confirm stop was untouched

Table 3. Trades with a documented rule violation (Yes) or an unclear record (Unclear). n = 8 and n = 2 of 40.

Summary. 8 trades (20%) have a documented violation, 2 (5%) are unclear, and 30 (75%) show no violation. Mean results were +0.31R (n = 30), -0.39R (n = 8) and -1.03R (n = 2) respectively. Violations were not uniformly harmful: T30 broke R3 and still returned +1.78R.

Chart 4. Risk-exceedance and rule-violation summary

Simulated data – n = 40 trades · groups are small; descriptive only

Chart 4. Left: counts of risk and rule flags (n = 40). Right: mean net result by rule status; groups are small and the comparison is exploratory.

Why a prior written plan matters. Adherence can only be judged against rules that existed before the trades. If rules are written or revised after seeing the results, almost any losing trade can be reclassified as a violation and any winning trade as discretion, which makes the comparison meaningless. A genuine audit therefore asks for the dated plan, and checks that each rule is specific enough to be tested (for example, 'size within 10% of plan' rather

than 'manage risk sensibly').

Violation versus unclear record. A documented violation is supported by evidence that the rule was broken (for example, an entry time earlier than the confirmation candle close). An unclear record means the evidence needed to decide is missing. T12 and T37 are classified Unclear for that reason; they should be resolved by obtaining evidence, not assumed to be violations or compliant. Notably, both resulted in losses, but with n = 2 this means nothing.

Section 7. Segment analysis

Setup	n	Wins	Win rate	Net R	Expectancy	PF (R)
Breakout	8	2	25%	-3.80R	-0.48R	0.38
Discretionary Other	7	3	43%	+1.41R	+0.20R	1.34
Range Reversal	8	4	50%	+1.17R	+0.15R	1.26
Trend Pullback	17	9	53%	+5.34R	+0.31R	1.61

Table 4a. Results by setup; n shown per segment (total 40).

Session	n	Wins	Win rate	Net R	Expectancy	PF (R)
Asian	5	1	20%	-2.20R	-0.44R	0.47
London	13	5	38%	-3.27R	-0.25R	0.63
London/NY Overlap	14	8	57%	+6.23R	+0.45R	1.96
New York	8	4	50%	+3.36R	+0.42R	1.82

Table 4b. Results by session; n shown per segment (total 40).

Instrument	n	Wins	Win rate	Net R	Expectancy	PF (R)
BTCUSD	9	5	56%	+4.81R	+0.53R	2.16
EURUSD	8	5	62%	+4.45R	+0.56R	2.44
GBPUSD	5	1	20%	-3.24R	-0.65R	0.23
USDJPY	11	5	45%	+0.75R	+0.07R	1.12
XAUUSD	7	2	29%	-2.65R	-0.38R	0.54

Table 4c. Results by instrument; n shown per segment (total 40).

Direction	n	Wins	Win rate	Net R	Expectancy	PF (R)
Long	26	14	54%	+7.68R	+0.30R	1.58
Short	14	4	29%	-3.56R	-0.25R	0.65

Table 4d. Results by direction; n shown per segment (total 40).

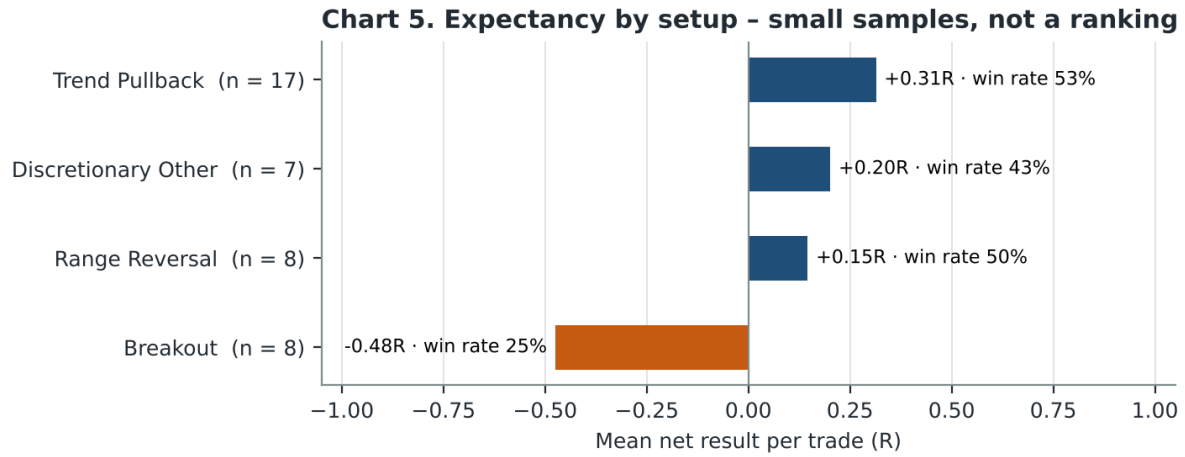

Chart 5. Mean net result per trade by setup, with n and win rate. Shown for transparency, not as a ranking.

Reading these tables. The largest segment has 17 trades and the smallest has 5. With groups this small, a swing of two or three trades changes a segment's sign. For example, Breakout had 2 wins from 8 trades and GBPUSD 1 win from 5; sets of that size routinely arise by chance even when the underlying win probability is unchanged. Session results are also entangled with rule flags: two of the five Asian-session trades (T14 and T26) are R2 violations. No setup, session, instrument or direction should be declared superior from this sample, and no significance tests are reported because the groups are too small to support them.

Section 8. Key findings

Finding 1. The positive expectancy is small and statistically indistinguishable from zero

Observed evidence	Expectancy +0.103R per trade; 95% CI -0.33R to +0.54R; profit factor 1.17 (R); win rate 45.0% versus break-even 41.1%; costs consumed about 20% of the pre-cost result.
Possible practical significance	With a thin margin over break-even, small changes in costs, slippage or win rate could remove the result.
Alternative explanations	Random variation over 40 trades; favourable or unfavourable market conditions; costs modelled as spread only.
Information needed to validate	At least 100 real trades with fills, commissions and slippage; the same metrics over rolling windows.

Finding 2. Trades with documented rule violations had weaker average results

Observed evidence	Violations: -0.39R (n = 8). No violation: +0.31R (n = 30). Unclear: -1.03R (n = 2). T30 violated R3 yet returned +1.78R.
Possible practical significance	If persistent, rule breaches would be a candidate source of avoidable loss, and tracking adherence would be worthwhile.
Alternative explanations	Eight trades is too few to separate rule effects from chance; the rule flags in this simulated set were authored by the preparer; violations may cluster in difficult market conditions.
Information needed to validate	A dated written plan, time-stamped entries and exits, and a larger sample; test each rule separately.

Finding 3. The two largest losses came from the two trades sized beyond tolerance

Observed evidence	T19 -1.54R (+50% size) and T33 -1.32R (+30% size) are the two largest losses in R. At planned size the same moves would have lost about -1.03R and -1.02R.
Possible practical significance	Position size is the one risk variable fully under the trader's control, and excess size lengthens drawdowns when stops are hit.
Alternative explanations	The stop-outs may have occurred at planned size regardless; oversizing could reflect an input error rather than a decision.
Information needed to validate	Order tickets, the sizing tool used, and whether size changed after entry.

Finding 4. The maximum drawdown was concentrated in one trading day

Observed evidence	Maximum drawdown 3.74R (peak T13 to trough T19). The three consecutive losses on 24 March (T17, T18, T19) total -3.59R. T19 was the third trade of the day after two losses (R5) and was oversized (R1).
Possible practical significance	A daily stop rule would have capped exposure on that day; drawdown control may depend more on same-day behaviour than on setup selection.
Alternative explanations	Three losses in a row can occur by chance; market conditions on that day may have hit all positions; the R-based and equity-based drawdowns peak at different trades (T19 versus T31).
Information needed to validate	Intraday timing of entries, daily P&L;, and whether the same pair or theme was traded repeatedly.

Finding 5. Segment performance varies, but no segment is large enough to conclude anything

Observed evidence	Breakout 2 wins in 8 trades; GBPUSD 1 in 5; Asian session 1 in 5; Short 4 in 14 versus Long 14 in 26. The largest segment has 17 trades.
Possible practical significance	These are candidates for investigation, not conclusions; they show where more data would be most informative.
Alternative explanations	Chance, the market direction during the period (long-biased results), overlap with rule flags (Asian session), and instrument-specific costs.
Information needed to validate	At least 30 trades per segment, pre-stated hypotheses, and market regime information.

Section 9. Recommendations and action plan

Prioritised by how directly each item is supported by the data and how easily it can be checked. These are process and measurement recommendations; none promises improved profitability.

#	Issue and proposed action	Evidence needed	Review criterion	Monitoring
1	**Position-size deviations (Findings 3).** Add a pre-trade size check against the planned-risk figure before order submission.	Order tickets; sizing calculation per trade	Actual risk within 10% of planned on every trade; zero R1 violations	Next 40 trades or 8 weeks, whichever is longer
2	**Same-day loss clustering (Finding 4).** Enforce a hard stop after two consecutive daily losses and log the time of each entry.	Time-stamped entries and exits; daily P&L;	No third trade after two losses; no daily loss above 2.5R	8 weeks
3	**Incomplete records (Section 6).** Require entry and exit screenshots and a stop-change log for every trade.	Screenshots; broker order history	100% of trades classifiable as Yes or No (no Unclear)	Next 40 trades
4	**Rule effect unproven (Finding 2).** Fix the written plan, date it, and track each rule separately rather than changing rules now.	Dated plan; per-rule adherence log	At least 30 trades per rule group before comparing expectancy with confidence intervals	6 months
5	**Thin margin and cost sensitivity (Findings 1, 5).** Record actual spread, commission and slippage per trade; state segment hypotheses in advance.	Fills, commissions, spreads; hypothesis list	Measured average cost per trade; expectancy CI width below 0.3R; at least 30 trades per segment	Next 100 trades

Table 5. Prioritised action plan. Criteria are examples a real client would adapt.

Section 10. Limitations and disclosures

- **Simulated data.** All trades, prices, dates, equity figures and flags are fictional. The outcomes and rule flags were authored by the preparer. Nothing here shows how a real strategy performs.
- **Small sample.** 40 trades give wide uncertainty (95% CI for expectancy spans about 0.87R). Segment groups of 2 to 17 trades cannot support ranking or significance claims.
- **Potential selection bias.** A real client may supply a selected subset of trades (for example, only recent or only well-documented ones), which can bias results. Completeness of the record should be verified against broker

statements.

- **Transaction costs and slippage.** Costs are modelled as spread only; commissions, swaps and realistic slippage are excluded and would reduce results.
- **Incomplete execution information.** There are no order tickets, fill timestamps or screenshots; T12 and T37 are unresolved for that reason.
- **Limits of causal inference.** Associations (for example, between rule flags and weaker results) do not show cause. Many factors, including market conditions, may explain them.
- **Description versus prediction.** The report describes a historical sample. It does not forecast results and should not be used to estimate future returns.
- **Not advice.** This document is educational and analytical. It is not investment, trading, tax or legal advice.

Section 11. Conclusion

A structured performance audit turns a trade log into answers to specific questions: whether results are distinguishable from chance, how large losses are relative to wins, whether risk was taken as planned, where drawdowns come from, and whether discipline problems are visible in the record. In this simulated case the data show a small positive average result that cannot be separated from zero, two oversized losing trades, one clustered losing day that explains most of the maximum drawdown, and records that are not complete enough to judge two trades.

A genuine assessment would need from a real client: a complete trade history exported from the broker (including cancelled orders and fills), a written trading plan with its date, the account equity and deposits or withdrawals, commissions and swaps, screenshots or journal entries supporting rule judgments, and a clear statement of how trades were selected for review. The output would then be findings and measurable process checks, not a promise of profit.

Appendix A. Trade log (simulated)

ID	Date	Instr.	Session	Setup	Dir.	Net USD	Net R	Risk >plan	Rule
T01	2026-03-02	USDJPY	Asian	Breakout	Long	197.80	+1.98	No	No
T02	2026-03-03	BTCUSD	London	Pullback	Short	-51.71	-1.01	No	No
T03	2026-03-03	XAUUSD	Overlap	Discret.	Short	-103.69	-1.02	No	No
T04	2026-03-04	EURUSD	Overlap	Pullback	Long	156.99	+1.56	No	No
T05	2026-03-06	EURUSD	Overlap	Pullback	Short	-104.81	-1.03	No	Yes
T06	2026-03-09	EURUSD	Overlap	Pullback	Short	148.89	+1.47	No	No
T07	2026-03-10	USDJPY	Overlap	Breakout	Long	-105.02	-1.03	No	No
T08	2026-03-11	EURUSD	Overlap	Pullback	Long	77.45	+0.76	No	Yes
T09	2026-03-12	XAUUSD	New York	Breakout	Long	-105.78	-1.04	No	No
T10	2026-03-13	EURUSD	London	Breakout	Short	-103.94	-1.03	No	No
T11	2026-03-16	EURUSD	Overlap	Pullback	Long	215.97	+2.16	No	No

Full records, including entry, stop, take-profit, exit, exposure and notes, are in the Excel and CSV files. Net USD is after transaction costs.

Appendix B. Verification and data-quality checks

Check	Result
Exactly 40 unique trade IDs, chronological order	Pass
Wins + losses = total trades	Pass (18 + 22 = 40)
Gross P/L - costs = net P/L, per trade and in total	Pass (239.30 - 94.83 = 144.47)
Winners + losers = net result (R and USD)	Pass
Gross P/L = exposure x signed price move, per trade	Pass
Actual risk % = exposure x stop distance / equity before trade	Pass
Net R = net USD / 1R USD, per trade	Pass
Equity roll-forward matches net P/L trade by trade	Pass
Stop-loss on the correct side of entry for every trade	Pass
Risk-exceeded flag matches actual vs planned risk	Pass
Independent recomputation of 19 headline metrics (plain Python, from CSV)	All matched
Segment tables each sum to 40 trades and net result	Pass
Charts and executive summary use the same computed values	Pass
Missing values in required fields	None; take-profit shows N/A for 3 documented trailing exits
Unresolved records	2 (T12, T37), flagged Unclear
